

the compounds **4a-4j** having oxazoles moiety. Cyclization of compounds **7a-7j** by thioglycolic acid in presence of anhydrous zinc chloride yielded compounds thiazolidinones **9a-9j**. The compounds **9h** and **9i** compounds exhibited better antibacterial activity than standard drug against *S. aureus*, *E. coli*, *P. vulgaris*. The compounds **9a**, **9b**, **9c**, **9d**, **9e**, **9f**, **9g** and **9j** exhibited better antibacterial activity than the compounds **5a-5j** having oxazoles moiety. The synthesized compounds were also tested for approximate lethal dose ALD<sub>50</sub> and were found to exhibit a higher value of ALD<sub>50</sub> i.e. more than 1000mg/kg i.p. except compound **9h** which exhibited ALD<sub>50</sub> of more than 2000mg/kg i.p. (maximum dose tested). As these compounds have shown high value of ALD<sub>50</sub> thus indicating good safety margin.

## CONCLUSION

While considering all the newly synthesized compounds of this series we may concluded that:

- 1 presence of thiazoles moiety has shown better antibacterial and antifungal activities than the compounds having oxazoles moiety.
- 2 2,6-dichlorophenyl substitution in thiazoles ring showed more potent activity than oxazoles ring.
- 3 Presence of electronegative atoms at 2 and 6 position in general beneficial for antibacterial and antifungal activities.

## ACKNOWLEDGEMENTS

Authors are thankful to Head, CDRI, Lucknow for providing analytical and spectral data for the compounds.
